

A separate description of the tests you ran on your program to convince yourself that it is indeed correct. Also describe any cases for which your program is known not to work correctly. This file should be in PDF format.

I used netcat to test the server before I built the client. It is super helpful for building requests, you can send anything and receive anything, tcp or udp. I also had a bunch of prints to stdout to verify the events that should be happening are happening. To test the client I also used netcat, I could send tcp and udp packets with netcat. When both of the parts were built (client and server) I ran both and tested them functionally, I tried each operation and stopping, I verified there were no errors.
